

## ECE232: Hardware Organization and Design

### Part 7: MIPS Instructions III

<http://www.ecs.umass.edu/ece/ece232/>

Adapted from *Computer Organization and Design*, Patterson & Hennessy, UCB

### Example: Array Access

- Access the ***i***-th element of an array ***A*** (each element is 32-bit long)

```
# $t0 = address of start of A
# $t1 = i
sll $t1,$t1,2      # $t1 = 4*i
add $t2,$t0,$t1    # add offset to the address of A[0]
                  # now $t2 = address of A[i]
lw $t3,0($t2)      # $t3 = whatever is in A[i]
```

## *if* statement

```
if ( condition ) {  
    statements  
}  
  
    # MIPS code for the condition expression  
    #(if condition satisfied set $t0=1)  
    beq $t0, $zero, if_end_label  
  
    # MIPS code for the statements  
  
if_end_label:
```

## *if else* statement

```
if ( condition ) {  
    if-statements  
} else {  
    else-statements  
}  
  
    # MIPS code for the condition expression  
    #(if condition satisfied set $t0=1)  
    beq $t0, $zero, else_label  
    # MIPS code for the if-statements  
    j if_end_label  
  
else_label:  
    # MIPS code for the else-statements  
  
if_end_label:
```

## ***while*** statement

```
while ( condition ) {  
    statements  
}
```

```
while_start_label:  
    # MIPS code for the condition expression  
    #(if condition satisfied set $t0=1)  
    beq $t0, $zero, while_end_label  
    # MIPS code for the statements  
    j while_start_label  
while_end_label:
```

## ***do-while*** statement

```
do {  
    statements  
} while ( condition );
```

```
do_start_label:  
    # MIPS code for the statements  
do_cond_label:  
    # MIPS code for the condition expression  
    #(if condition satisfied set $t0=1)  
    beq $t0, $zero, do_end_label  
    j do_start_label  
do_end_label:
```

## *for* loop

```
for ( init ; condition ; incr ) {  
    statements  
}  
  
    # MIPS code for the init expression  
for_start_label:  
    # MIPS code for the condition expression  
    #(if condition satisfied set $t0=1)  
    beq $t0, $zero, for_end_label  
    # MIPS code for the statements  
    # MIPS code for the incr expression  
    j for_start_label  
for_end_label:
```

## *switch* statement

```
switch ( expr ) {  
    case const1: statement1  
    case const2: statement2  
    ...  
    case constN: statementN  
    default: default-statement  
}
```

## MIPS code for *switch* statement

```
# MIPS code for $t0=expr
beq $t0, const1, switch_label_1
beq $t0, const2, switch_label_2
...
beq $t0, constN, switch_label_N
j switch_default
switch_label_1:
    # MIPS code to compute statement1
switch_label_2:
    # MIPS code to compute statement2
...
switch_default:
    # MIPS code to compute default-statement
switch_end_label:
```

ECE232: MIPS Instructions-III 9    Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass    Koren

## Logical AND in expression

```
if (cond1 && cond2){
    statements
}

# MIPS code to compute cond1
# Assume that this leaves the value in $t0
# If cond1=false $t0=0
beq $t0, $zero, and_end
# MIPS code to compute cond2
# Assume that this leaves the value in $t0
# If cond2=false $t0=0
beq $t0, $zero, and_end
# MIPS code for the statements
and_end:
```

ECE232: MIPS Instructions-III 10    Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass    Koren

## Switch Example

```

switch (i) {                                     // Assume i is in $s1 and j is in $s2;
    case 0: j = 3; break;
    case 1: j = 5; break;
    case 2: ;
    case 3: j = 11; break;
    case 4: j = 13; break;
    default: j = 17;
}

main:
    add    $t0, $zero, $zero                    # $t0 = 0, temp. variable
    beq    $t0, $s1, case0                      # go to case0
    addi   $t0, $t0, 1                          # $t0 = 1
    beq    $t0, $s1, case1                      # go to case1
    addi   $t0, $t0, 1                          # $t0 = 2
    beq    $t0, $s1, case2                      # go to case2
    addi   $t0, $t0, 1                          # $t0 = 3
    beq    $t0, $s1, case3                      # go to case3
    addi   $t0, $t0, 1                          # $t0 = 4
    beq    $t0, $s1, case4                      # go to case4
    j      default                             # go to default case
case0:
    addi   $s2, $zero, 3                       # j = 3
    j      finish                             # exit switch block
case1:
    addi   $s2, $zero, 5
case2:
    addi   $s2, $zero, 17
case3:
    addi   $s2, $zero, 11
case4:
    addi   $s2, $zero, 13
finish:

```

ECE232: MIPS Instructions-III 11 Adapted from Computer Organization and Design, Patterson&Hennessy, UCB, Kundu,UMass Koren

## Example: Conditional and unconditional branches

- Conditional branch: Jump to instruction L1 if register1 equals register2: `beq $s1, $s2, L1`  
Similarly, `bne`
- Unconditional branch:  
`j L1`  
`jr $s5` (useful for large case statements and big jumps)
- Convert to assembly:
 

```

if (i == j)
    f = g+i;
else
    f = g-i;

```

```

bne $s0, $s1, ELSE
add $s3, $s2, $s0
j EXIT
ELSE:
    sub $s3, $s2, $s0
EXIT:

```

ECE232: MIPS Instructions-III 12 Adapted from Computer Organization and Design, Patterson&Hennessy, UCB, Kundu,UMass Koren

## Example 2

- Convert to assembly:
- while (save[i] == k)  
    i += 1;
- i and k are in \$s3 and \$s5  
  and
- base of array save[] is in  
  \$s6

```
Loop:  sll    $t1, $s3, 2  
       add    $t1, $t1, $s6  
       lw     $t0, 0($t1)  
       bne    $t0, $s5, Exit  
       addi   $s3, $s3, 1  
       j      Loop  
Exit:
```

## Procedures

- Each procedure (function, subroutine) maintains a scratchpad of register values – when another procedure is called (the **callee**), the new procedure takes over the scratchpad – values may have to be saved so we can safely return to the **caller**
  - parameters (arguments) are placed where the **callee** can see them
  - control is transferred to the **callee**
  - acquire storage resources for **callee**
  - execute the procedure
  - place result value where **caller** can access it
  - return control to **caller**

## Registers

- The 32 MIPS registers are partitioned as follows:
  - Register 0 : \$zero                      always stores the constant 0
  - Regs 2-3 : \$v0, \$v1                      return values of a procedure
  - Regs 4-7 : \$a0-\$a3                      input arguments to a procedure
  - Regs 8-15 : \$t0-\$t7                      temporaries
  - Regs 16-23: \$s0-\$s7                      variables
  - Regs 24-25: \$t8-\$t9                      more temporaries
  - Reg 28 : \$gp                      global pointer
  - Reg 29 : \$sp                      stack pointer
  - Reg 30 : \$fp                      frame pointer
  - Reg 31 : \$ra                      return address

ECE232: MIPS Instructions-III 15    Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass    Koren

## Jump-and-Link

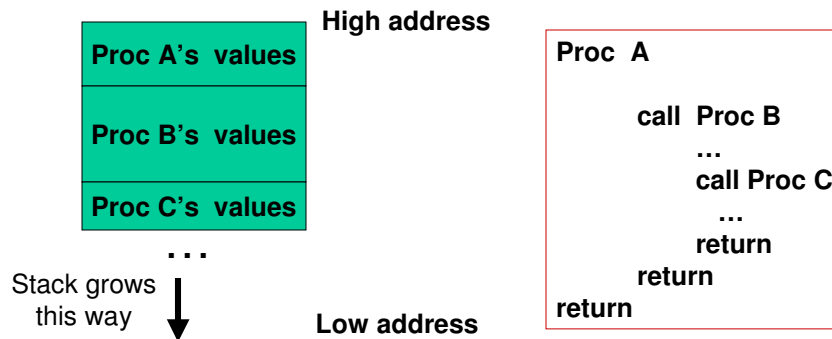

- A special register (not part of the register file) maintains the address of the instruction currently being executed – this is the **program counter (PC)**
- The procedure call is executed by invoking the jump-and-link (jal) instruction – the current PC (actually, PC+4) is saved in the register \$ra and
- jump to the procedure's address (the PC is accordingly set to this address)  
`jal    NewProcedureAddress`
- Since jal may over-write a relevant value in \$ra, it must be saved somewhere (in memory?) before invoking the jal instruction
- How do we return control back to the caller after completing the callee procedure?

ECE232: MIPS Instructions-III 16    Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass    Koren

## The Stack

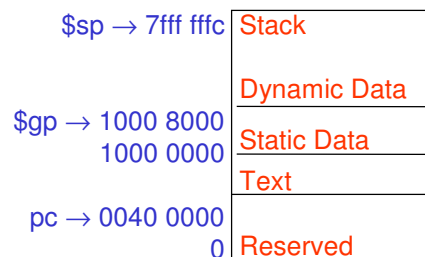

- The register scratchpad for a procedure seems volatile
- It may be modified every time we switch procedures
- A procedure's values are therefore backed up in memory on a stack

ECE232: MIPS Instructions-III 17 Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass Koren

## What values are saved?

Preserved	Not Preserved
Saved registers: \$s0-\$s7	Temporary registers: \$t0-\$t9
Stack Pointer: \$sp	Argument registers: \$a0-\$a3
Return Address Register: \$ra	Return registers: \$v0-\$v1
Stack above the stack pointer	Stack below the pointer

ECE232: MIPS Instructions-III 18 Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass Koren

## Storage Management on a Call/Return

- Arguments are copied into \$a0-\$a3; the jal is executed
- The new procedure (callee) must create space for all its variables on the stack
- After the callee creates stack space, it updates the value of \$sp
- Once the callee finishes, it copies the return value into \$v0, frees up stack space, and \$sp is incremented
- On return, the caller may bring in its stack values, ra, temps into registers
- The responsibility for copies between stack and registers may fall upon either the caller or the callee

ECE232: MIPS Instructions-III 19 Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass Koren

## Leaf Procedure Example

- Procedures that don't call other procedures
- C code:

```
int leaf_example (int g, h, i, j)
{ int f;
  f = (g + h) - (i + j);
  return f;
}
```

  - Arguments g, ..., j in \$a0, ..., \$a3
  - f in \$s0 (hence, need to save \$s0 on stack)
  - Result in \$v0

ECE232: MIPS Instructions-III 20 Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass Koren

## Leaf Procedure Example

```
int leaf_example (int g, h, i, j)
{ int f;
  f = (g + h) - (i + j);
  return f;
}
```

- MIPS code:

leaf_example:	
addi \$sp, \$sp, -4	
sw \$s0, 0(\$sp)	Save \$s0 on stack
add \$t0, \$a0, \$a1	
add \$t1, \$a2, \$a3	Procedure body
sub \$s0, \$t0, \$t1	
add \$v0, \$s0, \$zero	Result
lw \$s0, 0(\$sp)	
addi \$sp, \$sp, 4	Restore \$s0
jr \$ra	Return

## Non-Leaf Procedures

- Procedures that call other procedures
- For nested call, caller needs to save on the stack:
  - Its return address
  - Any arguments and temporaries needed after the call
- Restore from the stack after the call
- Example - **Recursion** (C code):
 

```
int factorial (int n)
{
  if (n < 1) return 1;
  else return n * factorial (n - 1);
}
```

  - Argument n in \$a0
  - Result in \$v0

## Non-Leaf Procedure Example

- **MIPS code:**

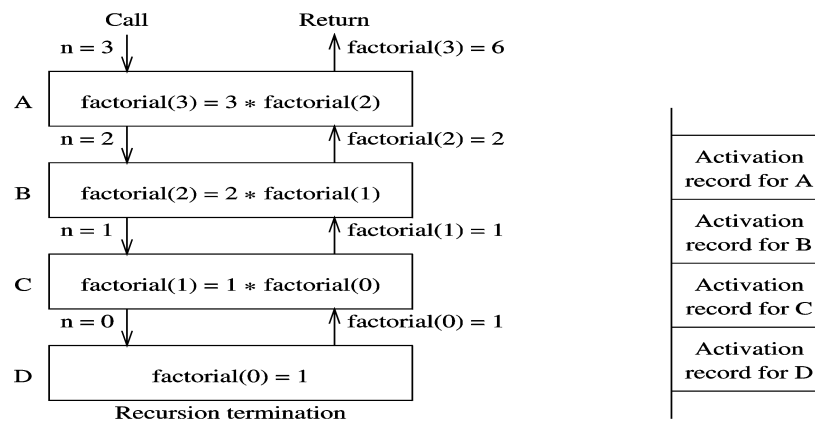

<b>factorial:</b>		
addi \$sp, \$sp, -8	# adjust stack for 2 items	
sw \$ra, 4(\$sp)	# save return address	
sw \$a0, 0(\$sp)	# save argument	
slti \$t0, \$a0, 1	# test for i < 1	
beq \$t0, \$zero, L1		
addi \$v0, \$zero, 1	# if so, result is 1	
addi \$sp, \$sp, 8	# pop 2 items from stack	
jr \$ra	# and return	
L1: addi \$a0, \$a0, -1	# else decrement i	
jal factorial	# recursive call	
lw \$a0, 0(\$sp)	# restore previous i	
lw \$ra, 4(\$sp)	# and return address	
addi \$sp, \$sp, 8	# pop 2 items from stack	
mul \$v0, \$a0, \$v0	# multiply to get result	
jr \$ra	# and return	

**Notes:** The callee saves \$a0 and \$ra in its stack space.  
Temps are never saved.

ECE232: MIPS Instructions-III 23 Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass Koren

## Recursion: Factorial

```
int factorial (int n)
{
    if (n < 1) return 1;
    else return n * factorial (n - 1);
}
```

ECE232: MIPS Instructions-III 24 Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass Koren

## Memory Organization

- The space allocated on stack by a procedure is termed the **activation record** (includes saved values and data local to the procedure)
- Frame pointer points to the start of the record and stack pointer points to the end
- Variable addresses are specified relative to \$fp as \$sp may change during the execution of the procedure
- \$gp points to area in memory that saves global variables
- Dynamically allocated storage (with malloc()) is placed on the heap

ECE232: MIPS Instructions-III 25 Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass Koren

## Summary

- The **jal** instruction is used to jump to the procedure and save the current PC (+4) into the return address register
- Arguments are passed in \$a0-\$a3; return values in \$v0-\$v1
- Since the callee may over-write the caller's registers, relevant values may have to be copied into memory
- Each procedure may also require memory space for local variables
- A stack is used to organize the memory needs for each procedure

ECE232: MIPS Instructions-III 26 Adapted from *Computer Organization and Design*, Patterson&Hennessy, UCB, Kundu,UMass Koren
